

Set can be created by using built in set function.

) Dictionary

A dictionary is an unordered collection of data values used to store data values like a map unlike other python data type that hold only a single data as an element.

Dictionary holds a pair of key and values. Key value is provided to the dictionary to make it more optimized.

Each key value in a dictionary is separated by a colon (:) whereas each key is separated by comma (,).

It is created by the built in function dict() just placing in curly braces.

Dictionary keys are case sensitive. If the same name but different cases of key will be treated distinctly.

Statements in Python:-

A python statement is an instruction that the python interpreter can execute.

Here the input is written in source code and executed by the python interpreter.

It is used for creating variables as well as displaying values.

Ex → `print ("Hello World")`
