

Immediate Addressing Mode :-

In this mode we specify the operand in the instruction itself in a single word instruction itself.
A single word instruction in the immediate mode consists of an operand which is used.

Register Mode :-

In this mode the operand exists in a register that is inside the CPU. In this case we select a specific register from a certain register field.
The k -bit field is capable of determining 2^k -bits registers.

Implied Mode :-

In this mode the operands are implicitly specified in the definition of instruction.
eg:- The Complement Accumulator refers to an implied mode because the instruction is implied to the accumulator register.

Register Indirect Mode :-

In this mode the instruction is available to define a particular register in the CPU, whose content provides the operand's address inside the memory.
In other words, any selected register can include the address of an operand instead of the operand itself.
