

Execution of python program

Type the program
Save it as filename.py (x.py)

Compile the program using python
Compiler. The Compiler Converts
the python program into another code
called Byte Code

Bytecode: It represents a fixed set of
instructions that represents all
operations like arithmetic,
Comparison, memory related
operation etc. which runs on
any operating system and hardware

It means that bytes instructions are system
independent or platform independent. The
size of each bytecode instruction is
1 byte and hence, they are called
byte code

Bytecode instructions are contained in the
file x.pyc
