

Next Step is to run the programme

If we directly give bytecode to the Computer it cannot execute then it is necessary to convert bytecode into machine code, so that our Computer can understand and execute it for this we should use PVM (Python Virtual machine).

PVM :- PVM uses an interpreter which understands the bytecode and converts it into machine code

An interpreter translates the program source code line by line. hence, it is slow. The interpreter that is found inside the PVM runs the Python program slowly to rectify this problem in some flavours of Python. A Compiler is added to the PVM

This Compiler also converts the bytecode into Machine code but faster than interpreter. This Compiler is called (JIT)
