Mappings

Non-type

In python the non-type data types represent an object that does not contain any value. To represent such an object we use ~~null~~ null in languages like C and Java. but in python we store none to represent an empty object and its data type is considered as

One of the uses of none is it is used inside the function as a default value of the argument.

When calling a function if no value is passed then the default value will be taken as none.
