

With the help of generating Control signal the hardwired Control unit is able to execute the instruction at Current type and a proper Sequence.

As compared with MPCU the HWCU is generally faster.

The generated opcode bits are received in the field of an instruction decoder which interprets the instr. and addressing mode of the instr. Now on the basis of addressing mode the instruction decoder sends the instruction signal ($INS_1 - INS_n$).

The information about the Current step must be known to the Control unit after that the step Counter is implemented which is used to contain the signal from ($T_1 - T_5$) (The o/p of step Counter will $T_1 - T_5$).
