

The program which is used to create the control signal are known as microprogram. It is placed on the processor which is a type of first memory and also known as Control store and Control word.

The instruction fetched in the first step and instruction from IR is updated.

~~Next~~ the instruction decode is going to be placed in IR which will decode the micro-instruction with the help of micro-instruction address generator.

Increment done in the 3rd step, which increments the Control word and corresponds to the starting address of micro program.

In this step the micro instruction contains of bit which is known as end-bit, so, in this Control unit the micro-program are stored with the help of Control memory or Control store which make the CU (Control unit) very flexible.
