

Semiconductor Memory : —

It is a type of digital memory technology that uses Semiconductors (Such as Silicon) to store and retrieve data. It is commonly used in electronic devices as a primary or secondary storage medium.

It is divided into 2 type :

1) Volatile memory

2) Non-Volatile memory

Volatile memory : —

In Volatile memory which requires power to store the data. Such as D-RAM (Dynamic Random Access memory) and S-RAM (Static Random Access memory).

Non-Volatile memory : —

The Non Volatile memory Such as (ROM) Read-Only-memory, flash memory and EEPROM (Electrically Erasable Programmable Read only memory) can be used as storing that data even when power is turned off.

Advantages : —

• Faster access time

• Higher data transfer rate

• Lower power consumption
