

Fetch : —

In this cycle the CPU retrieves the instruction from the memory. Here the instruction is typically stored at the address which is specified by PC.

The PC is said to autoimplemented mode which helps the PC to store the address of the next instruction.

Decode : —

In this cycle the CPU interprets the instructions and what operation needs to perform out. (It can be arithmetic or logical operation) (A-Lo)

This step involves identifying the opcode (Operational Code) and any operands that need to be executed that operation.

Execute : —

In this cycle the CPU performs the operations that are specified by an instruction.

Fetch operands : —

In sum CPU's some operands are phased separately before the execution cycle.

Store the result : —

In sum CPU's the result of sum instruction are stored during a separate cycle after the execution phase.
