

Request Processing Phase

Each time a request is made to the JSP, the `_jspService()` method is called automatically. This method generates dynamic content and sends it as a response to the client. Developers cannot override this method directly.

Destruction Phase

When the JSP is no longer needed or the server is shutting down, the `jspDestroy()` method is called. This method is used to release resources, close database connections, or perform cleanup tasks.

JSP Life Cycle Flow

JSP File (.jsp) → Translated to Servlet (.java) → Compiled to Bytecode (.class) → Loaded into Memory
Initialized (`JspInit`) → Request Processed (`_jspService`) → Destroyed (`jspDestroy`)

Method

Purpose

`JspInit()`

Executed once for initialization.
